APPARATUS AND METHODS FOR INTRALUMINAL PHOTOTHERMOFORMING

FIELD OF THE INVENTION

This invention pertains to devices for intraluminal implantation of polymeric materials in a human or animal patient and methods for delivering such materials.

BACKGROUND OF THE INVENTION

The application of polymeric materials to body tissues of human or animal patients is becoming increasingly important in medicine. Among the proposed uses of such materials are the alteration of tissue; the creation or preservation of lumens, channels or reservoirs for the passage or collection of fluids; the creation of matrices for the growth of tissue; the control of undesirable tissue growth; the delivery of therapeutic agents to a tissue surface; the ability to join a tissue surface to another tissue or an artificial implant; the ability to isolate or protect tissue or lesions to enable or mediate healing; and the ability to mediate the rate of substances or energy passing into, out of, or through tissue.

Although it has been recognized that the use of polymeric materials in vivo may offer significant therapeutic effects, to date such applications have met many limitations. For example, the methods for applying such polymers to tissue surfaces often require the use of pressure, heat or electrical energy exceeding limits of tolerability at the tissue site. Likewise various chemical effects associated

- 2 -

with such polymers have been found to be physiologically unacceptable.

Numerous methods for reshaping polymeric materials in vivo are known in the prior art. In particular, U.S. Patent No. 5,213,580 and International Publication WO 90/01969, both to Slepian et al., the entire disclosures of which are incorporated herein by reference, describe methods in which polymers having melting points slightly above physiological temperatures are implanted into a patient and in which such polymers are melted via contact with heated fluids and shaped using mechanical force provided by a balloon catheter. Unfortunately, many of the methods known in the art suffer from the need to use energy levels beyond those which are physiologically tolerable, or from the inability to sufficiently control the shape change and/or temperature of the polymeric material.

Typically, the primary limitation in prior art methods for the delivery of energy to an implanted device is the inability to direct the energy specifically to the device, while minimizing energy delivery to body tissue. For example, it is known in the prior art that polymeric devices such as stents may be delivered to specific locations in vivo using a balloon catheter. Such stents may be heated at the site by filling the balloon with a heated fluid. In that method, heat is conducted from the fluid in the balloon, through the balloon material, and into the stent. Since conduction is a relatively slow process and the balloon has a relative large thermal mass, energy is transferred not only to the stent, but also to the surrounding body tissues and fluids. The result is that undesired amounts of heat are transferred into the surrounding body tissues and fluids.

Accordingly, a need exists for apparatus for implanting polymeric materials in vivo that avoids the problems associated with the prior art. A need also exists for methods for delivering and reshaping materials in vivo which allow a physician to safely and easily introduce the material

- 3 -

into a patient, configure the material as desired, and deposit the material at a desired location for at least a therapeutically desirable period of time. A further need exists for materials and methods for reshaping such materials in vivo that offer the ability to reshape the materials while minimizing the amount of energy that is transferred to surrounding tissues and physiological fluids.

SUMMARY OF THE INVENTION

The present invention pertains to apparatus and methods for the delivery of polymeric material in vivo, and more particularly to the implantation of polymeric material into tissue lumens of human or animal patients. More particularly the invention relates to methods for photothermoforming a polymeric article in vivo, that is, modifying the shape of a polymeric article in vivo by using light to selectively heat the article to a temperature at which it is fluent, molding the article into a desired conformation, and allowing the article to become non-fluent in the desired conformation. Material from which the article is made is selected such that it is moldable at a temperature at which substantial damage to adjacent or proximate tissue does not occur.

Heating is achieved by irradiating, or illuminating the article with light of a wavelength or within a wavelength range at which the polymeric material readily absorbs, or at which adjacent tissue or body fluids do not significantly absorb. According to one aspect of the invention, the article is irradiated at a wavelength or within a wavelength range at which the polymeric material readily absorbs and at which adjacent tissue or fluids do not significantly absorb. This is achieved by providing polymeric material that relatively strongly absorbs the radiation provided, or by loading the polymeric material with a chromophore that readily absorbs the radiation. It is preferred that the light used to thermoform the polymer be of a wavelength that is not readily absorbed by body tissues or fluids, thereby

- 4 -

minimizing the amount of light absorbed by, and heat generated in, the tissue or fluid in the region of the thermoforming. According to one aspect of the invention visible or near-infrared light is provided locally to the polymeric material by an optical tip assembly on a delivery device.

The resulting shaped article provides a therapeutic benefit by acting, in one embodiment, as a stent to maintain patency through a blood vessel. Numerous other therapeutic shapes are contemplated as well.

According to one embodiment, the polymeric material has a chromophore such as a dye or pigment compounded therein. The chromophore is selected, in conjunction with a particular light source, to absorb light that is produced by the light source. The absorbed light is converted to thermal energy which acts to heat the polymer. According to one aspect of the invention, the chromophore is thermochromic. As an alternative to compounding the polymer with a chromophore, polymers that naturally absorb the wavelength spectrum of the light produced by the source may be used. The natural absorption spectrum of the material may result from the polymer in its native state, or alternatively, by the incorporation of one or more chromophores into the polymeric backbone or side-chains. In each case, however, it is necessary that the polymer satisfies other selection criteria such as biocompatibility and moldability.

By selecting a chromophore, or polymeric material, having maximum absorption characteristics at or near a particular wavelength or spectral range, in conjunction with a light source that emits at or near the particular wavelength or spectral range, the polymer is provided with the ability to be efficiently heated via light absorption. In this way, selective heating of the polymer with minimal heating of surrounding body tissues and fluids may be achieved.

Broadly, the apparatus comprises a catheter having a shaping element positioned near its distal end. The

- 5 -

polymeric material is positioned adjacent or near the shaping element, illuminated by light delivered by the catheter and thus heated to render it fluent, and molded by the shaping element into contact with a tissue lumen.

In one embodiment, the apparatus comprises a balloon dilatation catheter having an associated optical tip assembly. The polymeric material is positioned on the balloon, preferably in the form of a tube or sleeve which surrounds the balloon. The optical tip assembly serves to direct light to the polymeric material. The light may be provided from an external source. Upon absorption of the light, the polymeric material is heated to a temperature at which it becomes moldable. Inflation of the balloon causes the moldable polymeric material to expand outwardly, thereby pressing the polymer into contact with the tissue lumen. Alternatively, in cases in which the polymeric material can be reconfigured prior to molding (i.e., the polymeric material comprises a rolled sheet or a tube having axial pleats), the material is reconfigured using the balloon and then heated to mold it into conformance with an adjacent tissue surface.

According to another embodiment, the apparatus further includes a retractable sheath which is designed to encapsulate the polymeric material on the balloon as the material is guided to a treatment location in vivo. Once positioned, the sheath is retracted to expose the material and to allow the material to be heated and molded as described above. The sheath may include a tapered distal tip, formed of a flexible polymer, which expands radially over the balloon and polymeric material as the sheath is withdrawn over those structures. As an alternative, the tip may include at least one longitudinal slit which allows radial expansion of the tip.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates one embodiment of a laser balloon catheter suitable for delivery of a polymeric material;

- 6 -

FIGS. 2a and 2b illustrate one embodiment of a laser balloon catheter suitable for delivery of a polymeric material;

FIG. 3 is an illustration of a laser balloon catheter showing two embodiments of an optical emitter;

FIGS. 4a and 4b illustrate a second embodiment of a laser balloon catheter suitable for delivery of a polymeric material;

FIGS. 5a and 5b illustrate a retractable sheath suitable for use with the laser balloon catheters of FIGS. 1, 2 and 4;

FIGS. 6a and 6b are schematic illustrations of another embodiment of a device for providing a thick polymeric film on a luminal wall; and

FIGS. 7a and 7b are schematic representations of an optical emitter catheter for use with the device of FIG. 6b.

DETAILED DESCRIPTION OF THE INVENTION

The ability to selectively heat an implanted polymeric material using light in the visible or near-visible spectrum can be achieved using a light source which produces a wavelength spectrum that is not readily absorbed by body tissue. Light from the source is used to heat a polymeric material that is at least partially absorptive of the light in the spectral range. Even if only a portion of the light (e.g., 50%) is absorbed by the polymer, transmitted light will not be readily absorbed by the surrounding tissue and will have a minimal heating effect on that tissue. In this case, light which is not absorbed by the polymer is absorbed by a relatively large area of tissue as it penetrates beyond the polymer. As such, resultant heating occurs throughout a much larger volume of tissue. Since the temperature rise in the tissue is a function of energy absorbed within a unit volume of tissue, localized heating is significantly lower as compared to the heating caused by wavelengths that are readily absorbed, i.e., by a smaller volume of tissue. The requirement for wavelengths which have low tissue absorption

- 7 -

characteristics is necessary only to the extent that excess heating of the tissue does not occur or is undesirable at the particular treatment location.

Alternatively, it is possible to use light having a spectrum that is absorbed by body tissues and fluids provided that the polymeric material is highly absorptive of light in the spectral range. In this case, the polymer will absorb substantially all of the light, thereby minimizing the amount that is transferred to the body tissue and minimizing the heating effect of that light on tissue.

The polymeric materials of the present invention must satisfy various criteria, including molding temperature, crystallinity, absorption characteristics, bioerodability, physical strength, biocompatibility and light transmission and absorption characteristics. Each of these are discussed below.

Molding Temperature

The material must become either moldable or molten at a temperature that is not significantly injurious to tissue or surrounding physiological fluids if maintained at that temperature for the amount of time required to implant and shape the material. Additionally, the material must become moldable at a temperature above about 40 degrees C. That temperature has been selected as being a temperature that is greater than body temperatures associated with hyperthermia or fever (approximately 38-40 degrees C). The requirement of the minimum molding temperature is to prevent the material from spontaneously softening or melting in response to elevated, physiologically occurring body temperatures.

As used herein, the term "molding temperature" is used to describe a minimum melting temperature, T_m , or a glass transition temperature, T_g , at which the polymer may be plastically deformed using physiologically acceptable forces. Likewise, the melting or glass transition temperature must be below that at which significant

- 8 -

mechanical or thermal damage to body tissues occurs. The term "thermoforming" is used to describe the process wherein a polymeric article is heated to at least its molding temperature and then reshaped by external or internal forces.

Crystallinity and Physical Strength

It is preferred that the material have a substantially crystalline or semi-crystalline structure so that when heated to its melting temperature, it will undergo a rapid transition to a viscous fluid that will flow readily, yet remain cohesive, when subjected to molding forces associated with thermoforming. As an alternative, the material may be glassy or have a glassy component. In that case, if heated sufficiently above its glass transition temperature, the material will also flow readily and remain cohesive when subjected to molding forces.

The materials useful in the invention are termed "fluent" when in their moldable state. The actual viscosity of the fluent material that allows the material to be molded without significant mechanical disruption of the tissue depends upon the particular tissue and the method by which the material is molded. In general, it is preferred that the material be such that, once heated to its molding temperature, (i.e., rendered fluent), the material may be shaped or formed using a physiologically acceptable amount of force. Likewise, it is preferred that the molding temperature be low enough to prevent significant thermal damage during the molding process. The ability to be molded using a minimum amount of force reduces the possibility of tissue injury potentially occurring as a result of misuse or structural failure of the polymeric material or the force-supplying component.

Determination of an acceptable amount of force and thermal load depends upon at least a) the viscosity of the material in its moldable state, b) the length and/or thickness of the material, c) the geometric configuration of the material, and d) the temperature at which the material

- 9 -

becomes sufficiently fluent. Additionally, forces and thermal loads that may be physiologically acceptable on one type of tissue may not be acceptable on another. For example, physiologically acceptable forces and temperatures within bone tissue may far exceed the amount of force and heat that is physiologically acceptable on a blood vessel or other soft tissue. Thus, the physical characteristics of both the polymeric material and the tissue site must be considered in determining maximum physiologically acceptable forces and temperatures for molding the polymer.

It is preferred that the selected polymeric material be such that the amount of thermal energy needed to heat the material to its molding point can be transferred within a practical amount of time to thereby minimize the length of time required for the surgical procedure and to minimize the amount of heat conducted out of the material and into the tissue.

In one embodiment, the material is intended to provide mechanical support to tissue structures. In that embodiment, the material itself, and the ultimate therapeutic shape of the material, must provide a structure having sufficient mechanical strength to withstand forces exerted upon the shaped material during its functional lifetime in vivo. This requirement is especially significant when using materials that are expected to be biodegradable after their mechanically functional lifetime. Alternatively, the material need not be intended for structural support. Rather, the material may be used as a protective layer, a barrier layer, as an adhesive, or as a carrier of therapeutic agents. In that case, the material must be selected so that its function is not impaired either by biodegradation during its functional lifetime in vivo or by the process used to shape the material during implantation. The ability to provide varied degrees of mechanical support can be achieved by selecting differing polymeric materials or by altering the molecular weight distribution of materials comprising more

- 10 -

than one polymer. In general, materials having higher molecular weights will provide a higher modulus and greater support than those materials having a lower molecular weight. Additionally, the material must be selected such that the heating and reformation of the material do not degrade or otherwise alter the release characteristics of the material toward any therapeutic agents that may be incorporated into the material.

In some applications it is preferred that the material not completely cover, but only partially cover an area of tissue to be supported or otherwise addressed by the material. For example, the material may be applied to support a portion of a tissue lumen, rather than the entire lumen. The physical form may be varied to suit the final application. While relatively thin solid films or sheets are preferred for many applications, fenestrated or microporous sheets may also be used. Spun webs, with or without melt-bonding or calendaring, may also be of use. The material can include predefined perforations or apertures once transformed from a delivery configuration to its therapeutic configuration. If the device is intended to be delivered in the form of a hollow cylinder, the cylinder may be provided with a plurality of perforations which open or remain open once the cylinder has been expanded to a larger, therapeutic configuration. If the material is used as a support structure for an artery, the perforations may allow increased axial flexibility to facilitate delivery and reduce tissue erosion during and after implementation, improved perfusion of side branch vessels by decreasing the likelihood of obstruction of such vessels, and increased ingrowth of tissue for anchoring and encapsulation of the material.

Absorption Characteristics

The polymeric material should preferably absorb light within a wavelength range that is not readily absorbed by tissue, blood elements, physiological fluids, or water.

- 11 -

Although wavelengths in the spectral range of about 250-1300 nm may be used, wavelengths in the range of about 300-1000 nm are preferred, and wavelengths in the range of about 500-850 are especially preferred. In the case in which a chromophore such as a dye or pigment is incorporated into the polymeric material, the material itself must be sufficiently transparent to allow the light to reach and be absorbed by the dye or pigment.

For both the bioerodable and non-bioerodable polymers, chromophores and light sources suitable for use in the invention may be selected from dye or pigment materials and lasers corresponding to those materials including, but not limited to, the following:

<u>Wavelength (nm)/laser</u>	<u>Dye/Maximum Absorption</u>
457 Argon Ion	Acramine Yellow (420 nm)
488 Argon Ion	Acridine Orange (489 nm), Fluorescein (491 nm)
514 Argon Ion	Eosin Y (514 nm)
676 Argon/Krypton	Methylene Blue (661 nm)
647 Krypton 676	Jenner stain (651 nm), Methylene Blue (661 nm)
694 Ruby	Prussian blue (694 nm),
780 Semiconductor 780 810 820 830 850 870	Copper Phthalocyanine (795 nm in sulfuric acid), Indocyanine Green (775nm)
532 Neodymium:YAG (frequency X2)	Ethyl Eosin (532 nm in ethanol); Erythrosin B (525 nm); Eosin Y (514 nm)
355 Neodymium:YAG (frequency X3)	Acridine (358 nm)
266, Neodymium:YAG (frequency X4)	Prussian blue (260 nm),
All	Carbon black

- 12 -

The selection of light source and chromophore is not intended to be limited solely to those specified above. Rather, any combination that yields sufficient heating to render the polymeric material fluent may be used.

Any of a variety of methods known in the art of polymer processing may be used to form the polymeric material into its predeployment configuration and, if necessary, to compound chromophores into the material. Among the polymer processing methods contemplated are solvent casting, injection molding, extrusion, solvent extraction and compression molding.

The heating method of the present invention may be contrasted with conductive heating methods which use a heating element, as such techniques tend to require a greater thermal load and to heat more slowly, thereby having the potential to transfer significant amounts of heat to the surrounding body tissue or fluids. As noted previously however, absorption of light allows the polymeric article to be heated while transferring a minimum of energy to the surrounding tissue and fluids. This is achieved by selecting either a wavelength spectrum that is not readily absorbed by body tissue, a polymeric composition that absorbs substantially all incident energy in the wavelength spectrum, or a combination of these characteristics.

In one embodiment, the upper limit of the polymer temperature can be controlled using a dye which substantially stops absorbing optical energy once it reaches a certain temperature. Such so-called "thermochromic" dyes are commercially available from Clark R&D Limited of Arlington Heights, Illinois. Thermochromic dyes exhibit a constant absorption below a lower critical temperature T_L . Between T_L and an upper critical temperature T_U the absorption decreases from a constant value to nearly zero. Thermochromic dyes are further characterized generally in that the change of absorption with temperature is fully reversible. The incorporation of thermochromic dyes into

- 13 -

polymeric materials allows constant absorption of energy when the polymer is cool with a decreasing energy absorption as the polymer is heated. It is expected that the polymer temperature will reach a steady state at some point between T_L and T_U resulting from a balance between the energy absorbed by heat input from the light source and the energy lost by heat output to the surrounding tissue.

For example, Type 47 thermochromic dye available from Clark R&D absorbs, at room temperature, light in the wavelength spectrum between about 600 and about 850 nm. The dye has a T_L of 44 degrees C and a T_U of 58 degrees C. If this dye is compounded into a polymer having a melting temperature (T_M) that falls between T_L and T_U , the resulting polymeric material will absorb light in the 600-850 nm spectrum and begin to heat. Once the polymeric material is heated to a temperature above T_L , the absorption of the dye will decrease, thereby decreasing the rate of polymeric heating and preventing the polymeric material from achieving a temperature that may be harmful to it, and adjacent body tissue or surrounding body fluids. Once the temperature of the polymeric material reaches T_M , the polymer melts, allowing it to pave an adjacent tissue surface. However, since the temperature rise will decrease and reach a steady state level where the energy input (reduced due to decreased dye absorption) equals the energy output (mediated by thermal boundary conditions) an upper thermal limit is achieved. Thermochromism thus is essentially a feedback mechanism for obtaining uniform heating of the entire article despite possible non-uniformity of illumination. The hottest regions of the polymer will absorb less light, allowing other areas of the device to "catch up" in temperature during the heating stage. Thermochromic dyes can render instrumentation to measure temperature of the polymeric material unnecessary.

In addition, the use of thermochromic dyes may offer advantages if the emitter is eccentrically located inside a shaping element such as a balloon. Since power density from

- 14 -

the emitter is approximately related to the inverse or the inverse square of the distance between the emitter and the polymeric material, the power density would be much higher for a portion of polymeric material close to the emitter than for a portion of the material that is further away. When using conventional dyes, the result can be a non-uniform temperature around the shaping element, resulting in one portion of the polymeric material being much warmer than another. However, if a thermochromic dye is incorporated into the polymeric material, the material that is located closer to the emitter would rapidly reach its maximum temperature and level off, while material on a further portion of the polymeric material would reach the same maximum temperature, although more slowly. The result is that ultimately the entire polymeric article would reach a uniform temperature. Likewise, different thermal boundary conditions at the surface onto which the polymeric article is being applied could also, if conventional dyes are used, cause the polymeric article to become warmer in some sections than in others. This difference can also be reduced if thermochromic dyes are employed.

In still another embodiment, a thermochromic dye can be used in combination with a conventional dye. Thus, rather than reaching a steady state condition in which the thermal input is equal to the thermal output as a result of near zero dye absorption, a combination of thermochromic and conventional dyes would cause the heating to slow as the absorption of the thermochromic dye decreases. However, even if the thermochromic dye reaches a state of zero absorption, the heating level would continue to increase as a result of the presence of the conventional dye until a steady state is reached. By varying the relative proportions of conventional dye to thermochromic dye, the heating of the polymeric article can be tailored to a specific application.

- 15 -

Bioerodability

Although not intended to be limited as such, in one embodiment, the polymeric materials of the invention preferably are bioerodable. The term "bioerodable" as used herein is intended to encompass many modes of material removal, such as enzymatic and non-enzymatic hydrolysis, oxidation, and enzymatically-assisted oxidation. It is thus intended to include degradation, bioresorption and dissolution.

If the polymeric materials are to be bioerodable, they should be selected on the basis of their degradation characteristics to provide a sufficient functional lifespan for the particular application. In the case of arterial applications, a functional lifespan of 3-6 months is believed to be sufficient. In other therapeutic applications, (i.e., trachial, urinary, bronchial, bone lumens and the like) shorter or longer periods may be appropriate.

Suitable bioerodable polymeric materials include, but are not limited to, polymers, copolymers and blends of:

- A. Polyanhydrides (especially those made using melt condensation, solution polymerization, or with the use of coupling agents, aromatic acids, aliphatic diacids, amino acids (such as aspartic acid and glutamic acid), and the copolymers thereof).
- B. Copolymers of epoxy terminated polymers with acid anhydrides.
- C. Polyorthoesters
- D. Homo- and copolymers of α -hydroxy acids including lactic acid, glycolic acid, ϵ -caprolactone, γ -butyrolactone, and δ -valerolactone.
- E. Homo- and copolymers of α -hydroxy alkanoates.
- F. Polyphosphazenes.
- G. Polyoxyalkylenes, where alkene is 1 to 4 carbons, as homopolymers and copolymers including graft copolymers.

- 16 -

- H. poly(amino acids), including pseudo poly(amino acids).
- I. Polydioxanones
- J. Copolymers of polyethylene glycol with any of the above.

Suitable non-bioerodable polymeric materials include, but are not limited to, polymers, copolymers and blends of:

- K. Polyalkenes (such as polypropylenes)
- L. Polymethacrylates
- M. Polyacrylates
- N. Polyesters
- O. Polyamides (such as nylons)
- P. Polysaccharides (such as dextran)

In accordance with the invention, it is contemplated to blend or copolymerize materials to obtain desired properties in terms of melting point, strength, and biocompatibility.

Polycaprolactone homopolymers and copolymers are highly suitable bioabsorbable polymers for use in accordance with the invention, particularly for the prevention of abrupt closure or restenosis in a blood vessel, or for the creation of radially expanded lumens through a blood vessel, trachea, urethra or other tissue lumen. Such materials possess adequate strength in their solid form to structurally support soft tissue lumens. Additionally, once positioned and molded to a desired shape in a body lumen or hollow organ, the physical structure of such materials is sufficiently non-variable, in the period prior to its bioerosion, to maintain constant dimensions in the molded article. Thus, the materials provide structures such as stents that, although flexible, do not significantly deform in the period between implantation and degradation. Such dimensionally stable, shaped articles eliminate risks associated with known helical or spring metal stents which may have a tendency to

- 17 -

continue to expand once positioned in a lumen, thereby exerting continuous or increasing pressures on the lumen wall. Furthermore, polymeric stents of the type described conform, when fluent, to lumen irregularities. In the case of blood vessels, such conformity tends to avoid causing blood flow discontinuities which can contribute to thrombus formation. Stents formed of structural metallic or polymeric filaments do not closely conform to the lumen, thereby creating areas of blood stagnation and turbulence.

Polycaprolactones have a crystalline melting point of approximately 60 degrees C and can be deployed in vivo using the methods described herein. Additionally, such materials in their fluent state are well adapted for mechanical deformation to various degrees and into various configurations.

Polycaprolactone homopolymers and copolymers bioabsorb at rates that are advantageous in many applications in which biodegradability is desired. These materials can be designed to resorb as soon as three months after implantation or as long as three years after implantation. For example, polycaprolactone copolymerized with lactic or glycolic acids may resorb over a 3-9 month period, whereas polycaprolactone homopolymers may resorb over a 2-3 year period. The ultimate degradation product of polycaprolactones is a non-toxic, 6-hydroxy hexanoic acid having a pH close to neutral.

In contrast to the polycaprolactones, other bioabsorbable polymers such as polyglycolides and polylactides melt at temperatures on the order of approximately 180 degrees C, a temperature well above that tolerable by human tissue. However, these materials have glass transition temperatures of approximately 45 degrees C, thus they are moldable at physiologically tolerable temperatures and potentially useful in practicing the methods of the invention.

According to another embodiment of the invention polyanhydrides may be used. These materials are known for use as drug carrier matrices, and frequently have low glass

transition temperatures (in some cases near normal body temperature) which makes them mechanically deformable with only a minimum of localized heating. Furthermore, polyanhydrides offer biodegradation times spanning from several months to several years depending on the particular polymer selected.

Additionally, copolymerization may be used to alter the molding temperature of many families of polymers. For example, although poly(epsilon caprolactone) homopolymers exhibit a melting temperature of approximately 60 degrees C, poly(epsilon caprolactone-co-lactic acid) copolymers containing approximately 20% lactic acid exhibit a reduced melting temperature of approximately 45-50 degrees C.

In one embodiment of the invention, the polymeric material is a polycaprolactone polymer having an indocyanine green or copper phthalocyanine dye compounded therein. Such dyes readily absorb light in the 780-800 nm wavelength range, a range that is available from semiconductor diode lasers. Furthermore, wavelengths in this range are not readily absorbed by body tissues or fluids, thus the possibility of physiologically intolerable levels of heating by absorption of the light energy by such tissues and fluids is minimized.

It is advantageous in some cases to deliver a drug or other therapeutic agent from the thermoformed polymeric structure. Such delivery has advantages that are well-known to those skilled in the art of drug delivery, including the ability to deliver the therapeutic agent to a specific location in the body and to achieve concentrations of the agent that are locally higher than could be attained practically and safely when the agent is delivered systemically. Intended therapeutic agents include, but are not limited to, growth factors and growth factor antagonists, mitotic and antimitotic agents, antibiotics, antimycotics, antioxidants, anti-inflammatory agents, and substrate analogs for enzymes or receptors.

- 19 -

In one embodiment, the polymeric material may comprise a stent that is applied to the interior of a blood vessel following treatment of a stenosis by angioplasty. In that embodiment, the material is provided in the form of a hollow sleeve having a diameter that allows it to be guided through a blood vessel using percutaneous transluminal techniques. Upon positioning the sleeve at the treatment site, the sleeve is heated to its molding temperature and radially expanded into contact with the wall of the vessel. Once expanded, the device is allowed to cool and become non-fluent, or harden, thereby providing a vessel lining that offers structural support to maintain the vessel open and facilitate blood flow. As such, the device prevents abrupt post-surgical closure of the vessel. Alternatively, the material may be expanded prior to heating and molding, this alternative being described in greater detail hereinafter.

In its numerous applications, the applied lining, such as a vascular lining may incorporate various therapeutic and pharmaceutical agents to provide a means for local delivery of such agents at the treatment site. For that example, in the case of blood vessels, such agents may be employed to further reduce the likelihood of restenosis or other unwanted conditions at the site. These may be incorporated in the device, or coated onto or absorbed into it. The device may have multiple layers to control migration of the therapeutic agent.

If the device does not include the perforations discussed previously, the lining may also serve to isolate the vessel wall from physiological fluids, and in so doing, may avoid one mechanism for restenosis. Although the mechanisms for restenosis remain unclear, there is some evidence to suggest that angioplasty damages portions of the blood vessel, and these damaged portions become sites for cell growth via interaction with certain components in the bloodstream. If the damaged vessel portion is isolated from the bloodstream, the possibility exists that initiation of restenosis may be

- 20 -

avoided. Linings of this sort may be thinner, or less strong, than layers intended for use as structural supports.

In the embodiments described in detail below, including the preferred embodiment, the device and methods are used in intravascular therapy in situations where a guidewire is present, such as would be the case after a balloon angioplasty procedure. It is noted, however, that other cardiovascular treatments may not require certain elements shown in the figures. For example, if a catheter such as a guiding or sheath catheter remains in position from an earlier procedure, the guidewire (and thus the guidewire lumen) may not be necessary. Likewise, a central lumen may not be required if photothermoforming processes and materials are used in other organ systems, such as the intestines. Additionally, the devices depicted in the figures may include other features such as sensor or detector systems, or bypass lumens.

In one embodiment, the polymeric material may be delivered to the target site via a laser balloon catheter as shown in FIG. 1. The device 10 comprises an elongated flexible tube 11 (i.e., a catheter) having an article shaping element which comprises, for example, a radially expandable, inflatable balloon 12 positioned at its distal end. The tube 11 includes an inflation lumen 13 through which the balloon 12 may be inflated. The tube 11 also includes a central lumen 14 adapted to engage a guide wire. The central lumen 14 also allows passage by an optical tip assembly 15 which comprises a radial light diffuser 16 connected to a light source/controller 17 via an optical fiber 18.

The radial light diffuser 16 may comprise a flexible, translucent tube containing a light-scattering filler such as those described below with respect to FIGS. 2a and 2b. In one embodiment, the diffuser 16 contains a transparent or translucent adhesive containing light-scattering TiO_2 particles. The optical fiber 18 is connected between the light source/controller 17 and the radial diffuser 16 and

- 21 -

serves to transmit light between the source and the diffuser. When activated, the source produces light which travels through the optical fiber 18 and into the diffuser 16 causing the light to be scattered in a generally uniform, radial manner. As an alternative, portions of the diffuser may be masked or otherwise rendered non-translucent to produce radial or axial non-uniformities in the scattered light. Both the balloon 12 and the portion of the tube 11 in the region of the balloon should be substantially transparent to the light emitted from the diffuser.

The use of device 10 and other devices of the invention is described hereinafter. It should be understood that aspects of the invention described in greater detail below with respect to FIGS. 2-7 are applicable to the embodiment illustrated in FIG. 1.

Another embodiment is illustrated in FIGS. 2a and 2b. The device 21 comprises an outer elongated flexible tube 20 (i.e., a catheter) and an inner elongated flexible tube 22 positioned within the lumen of the outer tube 20. The inner tube 22 is longer than the outer tube 20 so as to cause its distal end 23 to extend distally beyond the distal end of the outer tube 20. An article shaping element, for example a radially expandable, inflatable balloon 24 is mounted on the distal end of the device such that the proximal end of the balloon 24 is secured near the distal end of the outer tube, and the distal end of the balloon is secured near the distal end of the inner tube. As will be described in detail below, a moldable polymeric article 19 is positioned on the balloon prior to its implantation at a desired treatment location.

The annular space formed between the inner wall of the outer tube and the outer wall of the inner tube forms an inflation lumen 25 through which the balloon may be inflated and expanded. Positioned within the annular space is at least one, and preferably a plurality of optical fibers 26, which extend from the proximal end of the device and have distal ends which communicate with an optical emitter

- 22 -

assembly 28. The optical emitter 28 is positioned within the interior of the balloon and preferably comprises an integral part of the inner tube 22 in the region in which the inner tube passes through the balloon. The article shaping element is not intended to be limited solely to a radially expandable balloon. Numerous other shaping elements, including but not limited to malecots and the like are contemplated as well.

In one embodiment, the optical emitter 28 delivers diffuse light within the shaping element and comprises a flexible, translucent tube 30 containing a light-scattering filler 32. The filler can comprise a translucent matrix containing light-scattering media such as titanium dioxide (TiO_2) particles. Other light scattering media include Zr_2O_3 , Ba_2SO_4 , diamond dust, glass beads, and combinations thereof, with or without TiO_2 . The translucent matrix can comprise, for example, an epoxy or other polymeric material which fills the annular gap between the translucent tube 30 and the inner tube 22, thereby forming the emitter as an integral element of the inner tube.

The proximal end of the device includes a hub assembly 27 having a port 31 to access the lumen through inner tube 22, a balloon inflation port 33 communicating with inflation lumen 25, and an optical fiber connector 35 which is attachable to a light source (not shown) to provide light through the optical fibers 26 to the optical emitter 28.

Two alternate embodiments for the emitter are shown in FIG. 3. In each of those alternate embodiments, the emitter may comprise the distal end of the inner tube, in the portion extending through the balloon and beyond its distal end. In the first alternate embodiment, shown in the upper portion of FIG. 3, the emitter 28 is affixed to the distal end of a catheter tube 40 using a taper joint 41, a lap joint, or other known joint structures to form a tubular assembly having a light diffusing distal end. The emitter preferably comprises a translucent polymer having an inherent light-scattering characteristic or a light-scattering medium

- 23 -

compounded therein. Optical fibers 26 communicating with the emitter are provided within the annular space between the outer and inner tubes or within lumens provided in the inner tube. In the second alternate embodiment, shown in the lower portion of FIG. 3, rather than comprising a two-piece construction as shown in the upper portion of FIG. 3, the catheter tube 40 may be translucent with light-scattering characteristics along all or part of its length. In that case the emitter is defined as that portion 29 of the tube 40 located distally to the distal ends of the optical fibers. It should be understood that FIG. 3 is a composite of two alternate embodiments of the device, and that in the actual device both the upper and lower portions would be the same.

The distal ends of the optical fibers 26 terminate within the light-scattering filler to allow light exiting from the fibers to be scattered in a substantially uniform radial manner. A light source/controller (not shown) is connected to the proximal ends of the fibers and serves to transmit light through the fibers into the emitter. By varying the concentration and composition of the scattering particles, and the number, position, and shape of the distal ends of the optical fibers, the intensity of the light field in the axial and circumferential directions can be controlled. Methods for achieving desired distributions of light intensity are known in the art and include simply arrays of scattering particles embedded in plastic as exemplified in U.S. Patent No. 5,169,395 to Narciso, Jr.; and gradients of scattering particles as exemplified in U.S. Patent No. 5,196,005 to Doiron et al.

It is noted that the emitter need not comprise a tube filled with a scattering material. Rather, a solid tube or annular sleeve of a material having inherent scattering properties such as polyethylene or PTFE may be substituted.

Returning to FIGS. 2a and 2b, the flexible, translucent tube 30 of the emitter comprises a flexible material which minimizes absorption of light in the wavelength spectrum

- 24 -

provided by the light source/controller. Numerous translucent polymeric materials can be used, including polyethylenes (PE), polyethylene terephthalates (PET), and polyfluoroalkylenes such as PTFE. Polyethylene is preferred. The light scattering filler 32 preferably comprises a transparent or translucent matrix, for example an epoxy adhesive, containing the light-scattering particles. The filler 32 is contained in the annular space created between the interior of the emitter tube 30 and the exterior of the inner tube 22. Like the emitter tube 30, the matrix containing the light-scattering particles must be substantially transparent to the wavelength spectrum of light produced by the light source/controller. Similarly, the balloon itself and its inflation medium must be transparent to the light in order to allow the light to pass through the balloon and heat the polymeric particle positioned on the balloon. A preferred inflation medium comprises a mixture of equal parts of saline and an iodinated contrast agent. Such a mixture is sufficiently transparent to light from the emitter and also radiopaque to aid fluoroscopic visualization.

As an alternative, the emitter may be formed integrally with the distal end of the optical fibers themselves. For example, the distal end of the fibers may be chemically or mechanically modified in a manner which causes the fibers to radiate laterally in the region of the modification. Thus, in one embodiment, the distal end of the fibers may be ground or chemically modified to "frost" the fiber, thereby to provide light scattering sites directly on the fiber surface. Optical fibers modified in this manner simplify manufacture of the devices in that the need to assemble a separate optical emitter for use with the device is eliminated.

In one embodiment, the inner tube 22, at least in the region of the optical emitter 28, is transparent to light in the wavelength spectrum being used to prevent "shadowing" of

- 25 -

the light. As an alternative, a reflective coating may be formed about the inner tube 22 in the region of the optical emitter to reflect back any light scattered toward the inner tube 22 by the light-scattering medium. If the inner tube 22 is translucent, the reflective coating can be provided on the inner surface of the tube. For light in the visible spectrum, the reflective coating preferably comprises a thin coating of silver, and for light in the infrared spectrum, the reflective coating preferably comprises a thin coating of gold. Such coatings can be deposited using any of a variety of known methods for depositing metal on polymeric surfaces, including but not limited to sputtering, ion bombardment, and ion-assisted vapor deposition. It is noted that these modifications are not mandatory, however, as satisfactory results can still be achieved even if the inner tube 22 in the region of the optical emitter 28 is not reflective of or translucent to the light. If the inner tube absorbs light in the wavelength spectrum provided to the polymeric article 36, the tube must be fabricated of a material that has a melting or glass transition temperature sufficiently high to avoid deformation of the tube during the heating and forming process.

A radiopaque marker 34 such as a band or ring of tantalum, gold, tungsten or silver, may be positioned on the device in order to aid the physician in determining the location of the distal end of the device during an implantation procedure. As shown in FIG. 2a, the radiopaque marker may be positioned within the interior of the balloon, however, other positions may be used as well. Furthermore, the device is not limited to the use of a single marker, but rather may make use of a number of such markers positioned at various places on the device.

The first and second elongated tubes can be formed of polymeric materials comprising, for example, polyethylenes, nylons, polyvinyl chlorides, polyether block amides, polyurethanes, and combinations and copolymers thereof. The

- 26 -

balloon preferably comprises a polymeric material such as polyethylene terephthalate, crosslinked polyethylene or composites thereof.

In order to ensure that the polymeric article does not stick to the balloon during the implantation procedure, the balloon may have a coating formed of a low surface energy material on its outer surface. Examples of such coatings include surfactants, hydrogels, fluoropolymers or silicone-based coatings. In the alternative, the surface of the balloon may be modified to a low energy surface using a plasma treatment, or the balloon itself may be made of a material with low surface energy (i.e., crosslinked polyethylene). Likewise a low surface energy properties can be provided on the polymeric article on surfaces which contact the balloon.

In an alternate embodiment, depicted in FIGS. 4a and 4b, the implantation device 50 can comprise an elongated tubular body 52 having at least two lumens extending from its proximal end. A central lumen 54 extends through the entire length of the tube, thereby allowing fluids and devices, such as guidewires, to pass entirely through the tube. At least one balloon inflation lumen 56 provides communication between the proximal end of the tube 52 and the interior of a radially expandable balloon 58 mounted near the distal end of the device. An optical emitter 60 is positioned within the balloon and serves to scatter light provided by at least one, and preferably a plurality of optical fibers 62 in a substantially uniform manner. The optical fibers can communicate with the emitter 60 either through the balloon inflation lumen 56, or, in the alternative, through a separate optical fiber lumen provided in the tubular body 52. A moldable polymeric article 36 is positioned on the balloon 58 prior to its implantation at a desired treatment location.

As in the embodiment described in connection with FIGS. 2a and 2b, the optical emitter 60 may surround a portion of

- 27 -

the tube 52 passing through the balloon, or, in the alternative, it can comprise the distal portion of the tube. Thus, the emitter can be of similar constructions as those described in connection with the earlier embodiments and as depicted in FIGS. 2a and 2b or FIG. 3. Also as in the earlier embodiment, one or more radiopaque markers 66, such as tantalum bands, may be positioned on the device to aid the physician in determining the location of the distal end of the device during an implantation procedure. Additionally, the proximal end of the device includes a hub assembly 27 having a lumen access port 31 to access the central lumen 54, a balloon inflation port 33 communicating with one or more balloon inflation lumens 56, and an optical fiber connector 35 in communication with the optical fibers 26.

When more than one balloon inflation lumen is provided, the ability to flow chilled fluid through the balloon is realized. For example, chilled fluid such as saline may be introduced into a first balloon lumen, allowed to flow through the balloon, and to exit the balloon through a second lumen. In this way, the polymeric article may be cooled, hastening its return to a non-fluent state and potentially preventing or minimizing thermal damage to tissue.

In each embodiment described herein, the device need not be limited solely to catheters having a central lumen passing entirely through the catheter shaft. Rather, the catheters can include a separate, shorter lumen having one end which exits the catheter at or near the distal end of the catheter shaft and a second opening somewhat proximal to the distal end of the shaft. Such so-called "rapid exchange" or "monorail" catheters are designed to facilitate catheter exchanges while maintaining positioning of a guidewire. Monorail catheters are known in the art, being described, for example, in U.S. Patent No. 4,762,129 to Bonzel.

In each embodiment, portions of the emitter or the shaping element optionally can be masked or otherwise rendered non-translucent to produce radial or axial

- 28 -

non-uniformities in the scattered light if non-uniform heating of the polymeric article 36 is desired.

In each embodiment, the device can be used as follows. The balloon is deflated and a polymeric article is positioned about its exterior. The balloon carrying the polymeric article is then advanced through a body lumen to position the polymeric article at a desired treatment location. Once positioned, light energy is supplied from the source through the optical fibers to the optical emitter or optical tip assembly. The light diffuses outwardly from the emitter and through the balloon (and through a tube according to the embodiment illustrated in FIG. 1). Upon transmission through the balloon, the light energy is absorbed by the polymeric material or by chromophores contained in the material. The energy absorption heats the polymeric material to at least its molding temperature. Once the molding temperature has been achieved, the balloon is inflated fully, thereby molding the material into conforming contact with the adjacent tissue surface. By providing an article that absorbs light in the wavelength spectrum supplied by the source, the article may be rapidly bulk heated with only minor conductive loss of heat to the surrounding tissue.

It should be understood that the sequence of heating and molding steps is not intended to be the sole method for implanting the polymeric article. For example, in an alternative embodiment, the balloon may be pressurized prior to heating of the polymeric article. In that embodiment, the pressurized balloon presses against the interior surface of the polymeric article which yields upon subsequent heating to its melting or glass transition temperature, thereby allowing the balloon to mold the material into conforming contact with the adjacent tissue surface. In still another embodiment, if the polymeric article is of a shape that can be expanded prior to becoming moldable, the article can be guided to a desired treatment location and then expanded by a partial inflation of the balloon. Upon heating the article to its

- 29 -

molding temperature, the balloon can then be fully inflated, thereby molding the previously expanded article into conforming contact with an adjacent tissue surface.

Once the article has been molded, the light energy is discontinued, thereby allowing the material to cool and become non-fluent. Either during or after the cooling process, the balloon is deflated and the catheter withdrawn, thereby leaving an expanded polymeric material lining positioned at the treatment site. In one embodiment, the polymeric article may comprise a relatively thin sheet of material that is positioned upon a tissue surface during a surgical procedure. Upon heating to a temperature above its molding temperature, the sheet may be pressed against the tissue surface, thereby causing it to conform to the surface shape. Alternatively, the sheet may be rolled about the balloon portion of the previously described balloon catheter. Upon heating to its molding temperature and expansion of the balloon, the sheet is caused to unroll and to be pressed into conforming contact with the interior of a body lumen. The ends of the sheet may be sealed to form a tubular structure. In another embodiment, the article may comprise a pleated, accordion-like shape which upon heating may be expanded to cover a surface.

According to still another embodiment, the sheet or pleated article may be first expanded, and then heated and molded in the manner described above.

In each of the embodiments described above, the device may include an elongated retractable sheath as an aid to maintaining the polymeric article on the balloon during the period at which the device is guided to the treatment location. As shown in FIG. 5a, the sheath 80 comprises a retractable elongated tube which is operatively coupled to or extends from the proximal end of the implantation device to a point distally beyond the shaping element. The distal end 82 of the implantation device may extend a short distance beyond the end of the sheath.

- 30 -

The sheath optionally can include a tapered distal tip 84 formed of a relatively soft, radially expandable material that may include at least one longitudinal slit 85 formed therein. The tip is affixed to the distal end of the sheath using, for example, a taper or lap joint. Alternatively, the tip 84 can be an integral part of the sheath 80. The use of a soft, pliable material and/or slits allows the tip to expand radially, thereby allowing the sheath to be withdrawn over the shaping element. The tapering of the tip provides a shaped surface which is adapted to minimize the possibility of damage as the distal end of the device is guided through a tissue lumen by providing a low profile leading edge.

The hub assembly 27 is as described above. However, an additional hub 81 is provided. Additional hub 81 is operatively connected to sheath 80 and serves as an actuator to retract the sheath and also as a hemostatic valve. A collar 83 positioned at the proximal end of hub 81 allows the practitioner to retract the sheath 80 and expose at least a portion of the implantable polymeric article 36. An optional port 87, in communication with the interior of the sheath, is provided. The port 87 allows fluid to be injected between the sheath and the portion of the device surrounded by the sheath if so desired.

As shown in FIG. 5b, upon positioning the polymeric article 36 at the desired location, the sheath is retracted to expose at least the article 36 and the underlying balloon 86. The tip is radially expandable with a minimum of force to allow the sheath to be retracted, thereby pulling the tip over the polymeric article, without dislodging the article from the balloon. The sheath is preferably formed of a polymeric material selected from the group consisting of fluoropolymers, high density polyethylenes, polyether block amides, polyurethanes, thermoplastic elastomers, and combinations and copolymers thereof. If used, the tapered distal tip preferably is formed of soft, flexible materials such as natural or synthetic rubbers, silicones, polyether

- 31 -

block amides, polyurethanes, thermoplastic elastomers, and combinations and copolymers thereof.

The use of a retractable sheath is optional, as static friction between the article and the balloon may be such that the article will not become dislodged from the balloon as the device is guided to a treatment location. Alternatively, other mechanical means such as end caps, or other retainers known in the stent art may be used to retain the article on the balloon. In particular, retaining sleeves or grommets of silicone or other polymers, positioned proximally and, optionally, distally of an article positioned on a balloon, can be used to retain articles in position on the balloon during passage through the body to a delivery site, or upon withdrawal of the retractable sheath.

Still another embodiment of the device is depicted schematically in FIGS. 6a and 6b. In that embodiment, the optical emitter is not included as part of the balloon catheter assembly, but rather, comprises a separate element that is inserted through the central lumen of the balloon catheter during the treatment procedure. More particularly, such a device 100 comprises a balloon catheter 102. The balloon catheter 102 comprises an outer elongated tubular shaft 104 and an inner elongated tubular shaft 105 having a shaping element 106 such as an inflatable balloon affixed near the distal ends of the shafts 104 and 105. One or more radiopaque markers may be positioned on the shafts 104 and 105. A central lumen 110 extending through the inner catheter shaft 105 is used to accommodate a guidewire 112, as well as an optical emitter as described below. If the shaping element 106 comprises an inflatable balloon, the balloon is inflated and deflated using a molding lumen 108. At least the portion of the inner shaft 105 in the area of the shaping element 106, and the shaping element itself, must be sufficiently transparent to allow light provided by an emitter positioned in the central lumen to pass through the shaft and the shaping element to an extent sufficient to

- 32 -

allow heating of a polymeric article mounted on the shaping element.

As shown in FIG. 6b, the device 100 further includes a separate optical emitter 114 that may be inserted through the central lumen 110 once the guidewire 112 is removed. The emitter may be of the type shown in FIGS. 7a or 7b. In the embodiment depicted in FIG. 7a, the optical emitter 114 has, at its distal end, a flexible, translucent emitter tube 116 containing a light scattering filler 118, such as that described previously. At least one optical fiber 122 has its distal end terminating within the light scattering filler 118. The proximal end of the optical fiber 122 terminates in an optical fiber connection 35 which is used to connect the optical fiber to the light source/controller (not shown). The emitter tube 116 is formed of a material that is substantially translucent or transparent to the light delivered through the optical fiber. Numerous translucent polymeric materials can be used, however, polyethylene is preferred.

As an alternative, shown in FIG. 7b, rather than mounting the emitter tube 116 on the distal end of the optical fiber 122, an emitter 130 comprising an emitter tube 116 and an emitter shaft 120 may be used. The emitter tube 116 may comprise a single integral shaft formed of a translucent or transparent material and loaded with the light scattering filler. The emitter tube 116 may be a separate element joined to the distal end of the emitter shaft 120, or it may be an integral element of that shaft. In the latter case, the emitter shaft can have light scattering properties along its entire length, or it may be a clear or translucent tube having scattering properties only at its distal end.

As still another alternative embodiment, at least one optical fiber having its distal end modified, for example by chemical or physical processes, so as to radiate light laterally can be substituted for the emitters described above. For example, disruption of the cladding of the

- 33 -

optical fiber, such as by abrasion, allows control of the lateral emission profile.

In use, the device illustrated in FIGS. 7a and 7b is positioned at a treatment site, typically post-angioplasty, using percutaneous transluminal catheterization procedures. Prior to insertion into a human or animal patient, the molding balloon is deflated and a polymeric article to be implanted is mounted on the balloon. If the procedure is to be carried out post-angioplasty, the angioplasty guidewire is left in place. However, if the procedure is to be carried out at some other time, a guidewire is first introduced into a patient and navigated until its distal end crosses the treatment location. The device is passed over the guidewire until the molding balloon and polymeric article is positioned at the treatment location. The guidewire is then withdrawn.

Once the guidewire has been withdrawn, the optical emitter 114 or 130 is inserted through the central lumen of the balloon catheter shaft 104 and advanced to position the emitter tube 116 in the portion of the shaft surrounded by the molding balloon 104. Light is then directed to the emitter to render the polymeric article positioned about the molding balloon moldable. As before, the molding balloon can be inflated either before, during, or after providing light to the emitter. Once the polymeric article has absorbed enough light to be heated to a point at which it becomes moldable, it is expanded, by the molding member, into contact with the adjacent lumen walls. Once the article has been expanded, the light supply to the emitter is terminated, the molding balloon is deflated, and the device is withdrawn, leaving the polymeric article in position at the treatment site.

Rapid solidification of the polymeric article after cessation of irradiation is desirable in many contemplated applications. Addition of nucleation centers into the polymeric material can accelerate the increase of strength of the material during cooling by increasing the crystallization

- 34 -

temperature and rate of the material. The use of nucleating agents is described in United States Patent No. 4,444,927 to Borysko, and in an article entitled, "A Nucleating Agent for Crystalline Olefinic Polymers", by Carroll, Modern Plastics, 108 (Sept. 1984), the entire contents of both of which are incorporated herein by reference for all purposes. For example, sucrose, lactose, dibenzylidene sorbitol, or a combination of these may be included in the polymeric material of the invention at a concentration of up to about 2 percent by weight, preferably about 0.5 percent by weight.

The polymeric article and the balloon material must be selected such that the article does not stick to the balloon surface regardless of whether the article is above or below its molding temperature. If necessary, a non-stick coating may be applied to the exterior of the balloon or to the interior of the article to allow the article to be released from the balloon following molding. When a non-stick coating is applied, it may be particularly advantageous to employ the above-described sheath or mechanical means such as end caps or other retainers to retain the article.

The method of the present invention is not intended to relate solely to systems in which the polymeric material cools and hardens by dissipating heat into physiological tissues and fluids in its immediate area. Rather, accelerated cooling may be achieved by contacting the heated material with a cooling fluid such as chilled saline, as discussed above.

In one embodiment of the invention, a means is provided for determining that the polymeric material has achieved its molding temperature in order to allow the physician to begin the thermoforming procedure. In that embodiment, the means used to reshape the material can also be used to indicate that the molding temperature has been achieved. For example, if the material is to be molded using a dilatation balloon surrounded by the material in its initial, predeployment configuration, the balloon may be pressurized continuously

- 35 -

during the heating process. Once the material becomes moldable, it will yield, allowing the balloon to expand. Such an expansion can be detected directly by the physician, or by a pressure or mass flow transducer in communication with the balloon inflation lumen. Other sensor systems may be used, including optical reading of temperature via a thermochromic dye, or direct temperature measurement by a probe. If a detector is used, it may also be used to shut off the light source used to heat the material once expansion occurs.

The use of thermochromic dyes, as discussed above, may facilitate accurate temperature measurement of the polymeric material. For example, in the case of polycaprolactone compounded with indocyanine, it has been observed that the material transforms from its characteristic green color to a translucent, clear appearance upon reaching its molding temperature. Subsequently, upon cooling and solidifying, the material returns to its previous green color. These colorations may be detected using remote reflectant photodetectors and optical fibers as are disclosed in U.S. Patent No. 5,009,655 to Daignault, Jr. et al.

As described previously, the polymeric article may contain apertures or other discontinuities which remain once the article has been molded. Likewise, the article may be any of a broad range of shapes suitable for molding in vivo. For example, the polymer may be in the form of a perforated tubular sleeve, a helical sleeve, a braided sleeve, or a plurality of discontinuous members of various shapes.

The polymeric materials of the present invention may be combined with a variety of therapeutic agents or living cells. The incorporation of therapeutic agents and/or cells is described in detail in the previously mentioned International Publication of Slepian et al.

In addition to blood vessels, the method of the present invention may be used for providing polymeric linings and coatings to other body organs including but not limited to

- 36 -

ureters, urethrae, bronchi, biliary and pancreatic duct systems, the trachea, the gut, the eye and the spermatic and fallopian tubes. The method can also be used in other direct clinical applications including, but not limited to, treatment of a blood vessel closure following coronary angioplasty, repair of vessel dissections, sealing of vessel wall flaps occurring either spontaneously or secondary to injury, sealing of aneurysms, and the like. In addition, the method provides a means for intra-operative sealing of vessel anastomoses during coronary bypass grafting, as well as a method for providing a "bandaged" smooth polymer surface following endarterectomy procedures.

As noted earlier, the method provides for "customizable" deployment geometry capabilities to accommodate numerous complex organ or vessel surfaces. The customized geometry can be provided using structurally stable polymers that may be tailored to correspond to the surface of a body tissue. By applying the polymeric material in moldable form, the material can be caused to coat uneven surface interstices. The resulting polymeric structure will facilitate improved structural support for numerous applications including eccentric coronary lesions which, by virtue of their geometry, are not well bridged using conventional stents.

The initial predeployment design and size of the polymeric structure will be dictated to some extent by the specific application and by the final deployed physical, physiological, and pharmacological properties desired. In the case of coronary artery applications, predeployment sleeves having a length of approximately 10-20 mm and a diameter of approximately 0.5-2 mm are preferred. The wall thickness of the resulting in vivo polymeric layer will vary depending on the nature of the particular application. In general, procedures adapted to provide a thin polymeric layer to a tissue surface will use polymer layers having a thickness of approximately 0.005-0.2 mm, while layers which are designed to provide structural support to a vessel may

- 37 -

vary in thickness from approximately 0.05-0.5 mm. The ultimate dimensions of the polymeric layer will depend upon the tissue to be treated. For example, within a bone lumen, a coating thickness of up to 5 mm may be beneficial. Thus, the suggested thickness are not intended as limitations.

A predeployment polymer tube for application in tissue lumens may be single or multi-layered and may be processed prior to insertion using laser or chemical etching, pitting, slitting or perforation depending upon the application. Additionally, the shape of any perforation may be further geometrically modified to provide various surface areas on the inner and outer surfaces of the polymeric article.

It is contemplated that the polymeric structures may be coated, either before or after placement, to obtain a surface suitable for the therapeutic surface. For example, the surfaces of a predeployed polymer may be further modified with bound, coated, or otherwise applied agents such as cyanoacrylates or biological adhesives to assist in adhering the material to a tissue surface. In particular, the surface may be coated to achieve or maintain biocompatibility or bioinertness with respect to blood, tissue or other materials, especially with respect to blood. Any of the biocompatible coatings known in the art may be used, such as heparin, or coatings containing polyethers or polyalkyleneglycols.

For applications involving the coronary arteries, the predeployment polymer tubes may include perforations or pores to provide symmetrical or asymmetrical expansion of the polymeric material. By using a polymer tube having openings or perforations, significant mechanical stability is provided, while minimizing the amount of foreign material (i.e., polymer) placed into the blood vessel. Perforations may encourage more rapid and complete encapsulation of the polymeric stent, which may be desired to prevent distal embolization.

- 38 -

The methods and materials have numerous other therapeutic applications. For example, the material may be used to provide a barrier layer on tissue surfaces to prevent the formation of connective tissue following trauma or surgical injury, or the material may be used to adhere tissue surfaces to other tissues or implants. In one embodiment, the adherent properties of the materials may be used to join severed nerve endings. These and other applications are described in detail in copending U.S. applications 07/843,485 and 07/870,540 to Hubbell et al., incorporated herein by reference.

The ultimate in vivo deployed geometry of the polymer dictates the final function of the polymer coating. Thinner applications allow the polymer film to function as a coating, sealant, partitioning barrier, bandage, and/or drug depot. Complex internal applications of thicker layers of material, such as intra-vessel or intra-luminal applications, provide increased structural support to maintain vessel or organ patency while providing the above features.

Vessel walls and lesions which are comprised mostly of fibromuscular components have a high degree of visco-elastic recoil. Such lesions require the application of an intra-luminal coating of greater thickness so as to impart more structural stability and to resist radial compressive forces. The inventive process may be used to provide structural stability and is thus generally applicable for the maintenance of intra-luminal geometry of all tubular biological organs or structures. It may be used in this manner following therapeutic return of normal architecture associated with various procedures known in the art.

In its simplest form the polymeric structure may be composed of an homogenous single layer. However, optimal light absorption and heat transfer within the device may be achieved by using gradients of absorber within the structure, or multiple layers of polymer with different concentrations of absorber. This can alleviate the attenuation of light at

- 39 -

the outer surface caused by absorption within the polymeric structure. Multiple layers may also be used to selectively deliver drug to the surrounding tissue, or to the lumen of the hollow organ or passage, by making one side of the structure less permeable to the drug.

Specific objects and features of the present process are best understood by way of illustration with reference to the following examples.

EXAMPLES

Example 1: Hydrophilic Dye in Poly(ϵ -caprolactone)

A hydrophilic dye, indocyanine green (IG), was dispersed in poly(ϵ -caprolactone), (PCL), a hydrophobic polymer, by solvent blending. The IG was dissolved in a drop of dimethylsulfoxide and was added to a 20% w/w solution of PCL in acetone. The resulting uniform solution was then cast in the form of films 130 micron (micrometer) and 250 micron thick, using a casting knife. The films contained 1 mg of IG per gram of PCL and the 250 micron films had an absorbance of 0.5 A.U. at 780 nm.

A sheet of the dye-containing polymer having a thickness of 250 micron was illuminated with an incident spot size of 1 cm diameter and raised to a temperature above its melting point of 63 degrees C by the application of approximately 4 joules of 780 nm light. The energy was applied at the intensity of 0.5 watts applied onto the 1 cm diameter spot for eight seconds. By demonstrating that the material sample could be sufficiently melted in this short period of time, it was shown that a phase change could be achieved in the polymer while using energy levels and time periods that are satisfactory for use in vivo.

The example further illustrates how a hydrophilic dye can be dispersed into a hydrophobic polymer, and also that near

- 40 -

infrared light, which is poorly absorbed by tissues, can be used to melt the polymer in a short period of time.

Example 2: Hydrophobic Dye in Poly(ϵ -caprolactone)

A hydrophobic dye, ethyl eosin (EE), was dispersed in PCL by solvent blending using acetone. The EE was dispersed in the PCL at a concentration of 1.5 mg per gram of PCL. A 200 micron thick film of polymer was solution cast. A sheet of polymer was illuminated with an argon-ion laser at an intensity of approximately 250 mW/cm^2 at all visible lines, including 514 nm. The melting took place within 5 seconds and could be detected by the change to a clear melt from the translucent semi-crystalline polymer film. The transmission of 514 nm light through this film was less than 5%. No photobleaching of the dye was evident over the period of the melting process.

This example illustrates how a hydrophobic dye can be dispersed into a hydrophobic polymer. It also illustrates that visible light, can be used to melt the polymer within a short period of time and that small amounts of light are transmitted through the polymer film. This would minimize any tissue heating and trauma that could possibly occur by irradiation from the visible light.

Example 3. Blood compatible coating for intravascular stenting

A polycaprolactone/ polyethylene oxide (PEG) block copolymer was synthesized by standard procedures. 37.5 g of PEG, molecular weight 8000, was heated in a 3-arm reaction flask at 90 degrees C overnight under vacuum, and then purged with nitrogen to complete drying. Caprolactone (12.5 g) was weighed into a sealed Erlenmeyer flask with a septum, and 29 microliters of a 10% w/v solution of stannous octanoate in chloroform was injected. The flask was shaken to dissolve the catalyst in the caprolactone. The caprolactone solution was added in an anhydrous manner (direct transfer) to the molten PEG, and the mixture was heated with stirring to 180

- 41 -

degrees C for 3 hours and allowed to cool under nitrogen purging until room temperature was reached. The polymer was dried overnight under vacuum at 90 degrees C. Polymer was removed from the reaction flask while molten, in a nitrogen-filled glove bag, and kept anhydrous until use.

Example 4. Paving devices for prototype clinical use in animals.

All steps below are at room temperature and in normal air unless otherwise stated. Indocyanine green (37.6 mg) was dissolved in 360 microliters of dimethylsulfoxide and diluted with 36 ml of chloroform. Polycaprolactone (3.65 g) of molecular weight about 80,000 was added to the dye mixture. The mixture was tumbled overnight in a capped tube to complete the dissolution. Thin films about 0.0015 inch (about 37.5 microns) thick were cast on glass plates, allowed to air dry, and then dried in a vacuum oven at 50 degrees C overnight.

The film was stripped and folded to be four layers thick, and then pressed at 80 degrees C in a Carver press at 5000 psi (about 350 bar) to a thickness of about 0.0045 - 0.0050 inch (113 - 125 microns). Apertures, about 1 mm in diameter, were made in the film using a template and sharpened hypodermic needle tubing. About 25% of the surface area was removed, in a square array. Radiopaque markers (platinum foil) were affixed beneath a single layer of the same film, and the assembly was bonded by passage through a laminating press set at 65 degrees C.

Some devices were coated at this stage with the polymer of example 3. They were affixed to a piece of filter paper, and sprayed for 5 to 10 seconds with a freshly-prepared solution containing 10% of the example 3 polymer in 75:25 v/v acetone/water, using an "EFD Valematic" atomizer (Nolico Co., Hampton Falls, New Hampshire) operating at about 10 psi (0.67 bar). Coated devices were dried about 15 min. at room temperature, and then rinsed by dipping for about 1 minute

- 42 -

into distilled water. After patting with filter paper to remove moisture, the devices were again rinsed in fresh distilled water, patted dry, and vacuum dried overnight. Comparison of coated and uncoated surfaces by contact angle measurement showed a substantial increase in hydrophilicity of the coated device surfaces (decrease in contact angle with water).

Devices, about 10 mm by 19 mm, were rolled on a 0.042 inch (1050 micron) mandrel to obtain a roll about 10 mm long along the mandrel. The roll was secured with Teflon tape and heat set at 50 degrees C at least 12 hours. The rolled devices were cold sterilized with ethylene oxide (room temperature, 18 hours, Anderson system) while placed in standard EtO sterilization bags.

Example 5. Deployment in animals.

Devices of Example 4 were positioned on the balloon of a custom balloon angioplasty catheter, which had an optically transparent guide wire lumen continuing through the balloon region, and secured with a moveable sheath. After insertion of the catheter through the carotid artery of a dog and localization in the iliac artery by standard techniques, the guidewire was removed and replaced with an optical fiber with a 15 mm diffuser tip, which had been calibrated to emit 3 watts of power when powered by a diode laser operating at about 800 nm (Rare Earth Medical). The sheath was then retracted under radiographic observation, and the balloon was inflated at 6 atmospheres to deploy the device. Laser energy was emitted for 45 to 60 seconds, while 6 bar pressure was maintained, to mold the device to the artery wall and to seal it to itself where there was overlap. Pressure was maintained for an additional 5 minutes while the device cooled, and then the balloon was deflated and the catheter was removed, leaving the device as a coating in the artery.

(The times were chosen after a simulation in an excised cow artery kept in a 37 degree bath, in which a thermocouple

- 43 -

was positioned between the device and the artery wall. Temperature at the end of 60 seconds of illumination was about 65 degrees, while the material had returned to blood temperature after 5 additional minutes.)

Example 6. Delivery of Therapeutics

Heparin was spray-dried to a fine powder by pumping a 2% w/v solution, in distilled water, through a Lab-PlantTM spray drier at 12 ml/min, 100 degrees C inlet temperature. Final particle size was in the range of 1-10 microns diameter. Six grams of polycaprolactone was dissolved in 60 ml of chloroform. To 20 ml of this solution, spray-dried heparin was added to a final concentration of 5%, 10% and 30% w/w (i.e., 1, 2 and 6 grams). The solutions were homogenized for 7 minutes using a Virtis homogenizer. Films were cast, and 4 layers of film were laminated as in example 4.

Square devices 1 cm by 1 cm were placed in 1.5 ml microcentrifuge tubes containing 1 ml phosphate buffered saline preserved with sodium azide. Samples were incubated at 37 degrees C. Buffer was periodically removed for analysis and replaced with fresh buffer. Heparin content of the buffer was analyzed by the standard Azure B method. Retention of heparin after the first 12 hours was about 70%, 45% and 20% of the amount contained in the 5%, 10% and 30% loadings respectively. Heparin continued to elute slowly over the next 500 hours, at which point about 37%, 20% and 10% respectively was retained in the devices.

Example 7. Rapid Crystallization.

The time course of the experiment of Example 5 is too long for use in certain situations, such as human coronary arteries. Devices were made as in Example 6, but containing 0, 1% and 10% of dibenzylidene sorbitol (MilladTM 3905), and then rolled for delivery as in example 4. Devices were tested in a tube simulating an artery. After a standard

- 44 -

heating pulse, the minimum time to obtain sufficient strength development to allow detachment of the balloon was 146 seconds, 71 sec., and 39 sec. for 0,1 and 10% Millad nucleator, respectively.

Equivalents

Although specific features of the invention are included in some embodiments and drawings and not others, it should be noted that certain features may be combined with other features in accordance with the invention.

In addition, it should be noted that the invention is not intended to be limited to the specific materials and construction described herein.

It should be understood that the foregoing description of the invention is intended to be merely illustrative thereof, that the illustrative embodiments are presented by way of example only, and that other modifications, embodiments, and equivalents may be apparent to those skilled in the art without departing from its spirit. Having thus described the invention, what we desire to claim and secure by Letters Patent is:

- 45 -

CLAIMS

1. A method for providing a polymeric material on a tissue surface which comprises the steps of:

- a) providing a light source that produces light at a predetermined wavelength;
- b) providing a polymeric material that absorbs said light;
- c) positioning the polymeric material on the tissue surface;
- d) illuminating the polymeric material with sufficient light from the light source to heat the material to at least the temperature at which the material becomes fluent;
- e) molding the fluent material into a desired shape within the body of a patient; and
- f) allowing the material to cool and become non-fluent.

2. A method as in claim 1 wherein the material is molded so that at least one surface of the material is in intimate and conforming contact with the tissue surface.

3. A method as in claim 1 wherein the tissue surface comprises an interior surface of a tissue lumen or a hollow organ.

4. A method as in claim 2 wherein the tissue comprises a blood vessel.

5. A method as in claim 1 wherein the light produced by the light source is of a wavelength range that is not readily absorbed by the tissue surface.

6. A method as in claim 5 wherein the wavelength range of the light is in a spectrum of between about 500 and 850 nm.

7. A method as in claim 1 wherein the light source comprises a laser.

- 46 -

8. A method as in claim 1 wherein the polymeric material is selected from the group consisting of polymers of caprolactones, anhydrides, lactides, glycolides, oxyalkylenes, and combinations thereof.

9. A method as in claim 8 wherein the polymeric material comprises a copolymer of at least two moieties selected from the group consisting of caprolactones, anhydrides, lactides, and glycolides.

10. A method as in claim 1 wherein the polymeric material further contains a chromophore.

11. A method as in claim 10 wherein the chromophore comprises a dye or pigment.

12. A method as in claim 11 wherein the dye or pigment is selected from the group consisting of indocyanine, eosin, copper phthalocyanine, and combinations thereof.

13. A method as in claim 1 wherein the polymer is biodegradable.

14. A method as in claim 1 wherein the fluent polymer is molded using a catheter having a radially expandable portion.

15. A method as in claim 15 wherein the radially expandable portion of the catheter comprises a dilatation balloon.

16. A method as in claim 1 which further includes the step of determining when the polymeric material becomes fluent.

- 47 -

17. A method as in claim 16 wherein the determining step includes monitoring the pressure or volume of an expandable portion of a catheter.

18. A method as in claim 1 wherein the polymeric material contains a therapeutic material.

19. A method as in claim 1 wherein the polymeric article is made of multiple layers.

20. A method as in claim 19 wherein the layers have different compositions.

21. A method as in claim 1 wherein the polymeric article is further coated at least in part.

22. A method as in claim 21 wherein the coating is biocompatible.

23. A method as in claim 22 wherein the coating is a block copolymer in which one block is the material of the polymeric article, and the other is polyethylene oxide.

24. A method as recited in claim 1, and further comprising the steps of::

a) providing a device which comprises:

i) an elongated tubular shaft having a distal end, a proximal end, and a lumen in communication with an article shaping element;

ii) an article shaping element positioned near the distal end of the tubular shaft;

iii) at least one optical fiber having a distal end communicating with an optical emitter, the emitter positioned in the proximity of the article shaping element;

- 48 -

iv) an elongated, retractable sheath operatively coupled to the proximal end of the elongated tubular shaft and extending to the distal end of the elongated tubular shaft; and

v) a polymeric article positioned about at least a portion of the article shaping element, the article comprised of a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape;

b) guiding the distal end of the device to a location in the patient to position the moldable polymeric article at a desired treatment location;

c) retracting the sheath to expose at least a portion of the polymeric article;

d) directing light through said at least one optical fiber to the emitter to provide light to the polymeric article via the article shaping element to render the article moldable;

e) molding the polymeric article via the article shaping element into contact with tissue at the treatment location;

f) optionally allowing the polymeric article to cool and become less fluent;

g) releasing the polymeric article from contact with the article shaping element; and

h) withdrawing the device from the patient, thereby leaving the polymeric article at the treatment location.

25. A method as in claim 24 wherein the article shaping element is radially expandable.

26. A method as in claim 25 wherein the article shaping element comprises a radially expandable balloon.

- 49 -

27. A method as recited in claim 1, and further comprising the steps of:

- a) providing a device which comprises:
 - i) a first elongated tubular shaft having a proximal end, a distal end, and a lumen;
 - ii) a second elongated tubular shaft having a proximal end, a distal end, and a lumen, the second shaft being positioned within the lumen of the first shaft and the distal end of the second shaft extending beyond the distal end of the first shaft;
 - iii) a radially expandable balloon having a proximal end and a distal end, the distal end of the balloon being secured near the distal end of the second shaft and the proximal end of the balloon being secured near the distal end of the first shaft;
 - iv) at least one optical fiber having a distal end communicating with an optical emitter, the emitter positioned at least partially within the balloon; and
 - v) a polymeric article positioned about at least a portion of the balloon, the article comprised of a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape;
- b) guiding the distal end of the device to a location in the patient to position the moldable polymeric article at a desired treatment location;
- c) directing light through said at least one optical fiber to the emitter to provide light to the polymeric article to render the article moldable;
- d) inflating the balloon to radially expand the polymeric article into contact with tissue at the treatment location;
- e) optionally allowing the polymeric article to cool and become non-fluent;

- 50 -

f) deflating the balloon to thereby release the polymeric article from the balloon; and

g) withdrawing the device from the patient, thereby leaving the polymeric article at the treatment location.

28. A method as recited in claim 1, and further comprising the steps of:

a) providing a device which comprises:

i) a first elongated tubular shaft having a proximal end, a distal end, and a lumen;

ii) a second elongated tubular shaft having a proximal end, a distal end, and a lumen, the second shaft being positioned within the lumen of the first shaft and the distal end of the second shaft extending beyond the distal end of the first shaft;

iii) a radially expandable balloon having a proximal end and a distal end, the distal end of the balloon being secured near the distal end of the second shaft and the proximal end of the balloon being secured near the distal end of the first shaft;

iv) at least one optical fiber having a distal end communicating with an optical emitter, the emitter at least partially positioned within the balloon;

v) an elongated, retractable sheath extending from the proximal end of the first shaft to the distal end of the second shaft, the sheath being retractable to expose at least a portion of the balloon; and

vi) a polymeric article positioned about at least a portion of the balloon, the article comprised of a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape;

b) guiding the distal end of the device to a location in the patient to position the moldable polymeric article at a desired treatment location;

- 51 -

c) retracting the sheath to expose at least a portion of the polymeric article;

d) directing light through said at least one optical fiber to the emitter to provide light to the polymeric article to render the article moldable;

e) inflating the balloon to radially expand the polymeric article into contact with tissue at the treatment location;

f) optionally allowing the polymeric article to cool and become non-fluent;

g) deflating the balloon to thereby release the polymeric article from the balloon; and

h) withdrawing the device from the patient, thereby leaving the polymeric article at the treatment location.

29. In a method of applying a polymeric article to a tissue surface of an animal, including a human, by bringing the article to a temperature at which it becomes fluent, molding the article at the temperature to conform the article to the tissue surface, and allowing the article to become non-fluent, the improvement comprising:

irradiating the article to bring it to the temperature at which it becomes fluent.

30. The improved method as recited in claim 29, further comprising selecting a light source having an emission spectrum, and selecting the article, such that the article absorbs substantially within the emission spectrum of the light source.

31. The improved method as recited in claim 29, further comprising selecting a polymeric article which includes a chromophore compounded therein.

32. The improved method as recited in claim 31, wherein the chromophore is thermochromatic.

- 52 -

33. The improved method as recited in claim 31, wherein the light source is a laser.

34. The improved method as recited in claim 33, wherein the article is irradiated by directing light from the laser through an optical fiber which is carried by a catheter to a light diffusion material near the article.

35. The improved method as recited in claim 33, wherein the article is irradiated by directing light from the laser through an optical fiber which is carried by a percutaneous intraluminal catheter to a light diffusion material near the article.

36. The improved method as recited in claim 100, further comprising actively cooling the article to allow it to return to a non-fluent state.

37. The improved method as recited in claim 36, further comprising actively cooling the article by passing chilled fluid through a catheter that contacts the article.

38. The improved method as recited in claim 29, further comprising molding the article by placing it between a forming member carried by a catheter and a tissue surface and expanding the forming member to mold the article to the tissue surface.

39. The improved method as recited in claim 38, further comprising actively cooling the article by passing chilled fluid through a first lumen in the catheter to the forming member in contact with the article, allowing the fluid to contact the forming member, and allowing the fluid to exit the forming member through a second lumen in the catheter.

- 53 -

40. A method for implanting a moldable polymeric article into a patient which comprises the steps of::

a) providing a device which comprises:

i) an elongated tubular shaft having a distal end, a proximal end and a lumen communicating with an article shaping element;

ii) an article shaping element positioned near the distal end of the tubular shaft;

iii) at least one optical fiber having a distal end communicating with an optical emitter, the emitter positioned in the proximity of the article shaping element; and

iv) a polymeric article positioned in the proximity of at least a portion of the shaping element, the article comprised of a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape;

b) guiding the distal end of the device to a location in the patient to position the moldable polymeric article at a desired treatment location;

c) directing light through said at least one optical fiber to the emitter to provide light directed at the polymeric article to render the article moldable;

d) molding the polymeric article via the article shaping element into contact with tissue at the treatment location;

e) optionally allowing the polymeric article to cool and become less fluent;

f) releasing the polymeric article from contact with the article shaping element; and

g) withdrawing the device from the patient, thereby leaving the polymeric article at the treatment location.

- 54 -

41. A method as in claim 40 wherein the article shaping element is radially expandable.

42. A method as in claim 40 wherein the article shaping element comprises a radially expandable balloon.

43. In a device for applying a polymeric article to a tissue surface of an animal, including a human, the device including a catheter having a proximal end and a distal end, an article forming member near the distal end of the catheter, and a lumen passing from the proximal end of the catheter to the article forming member, the improvement comprising:

an electromagnetic radiation emitter near the distal end of the catheter.

44. The improved device as recited in claim 43, wherein the electromagnetic radiation emitter produces an emission spectrum that is substantially absorbed by the polymeric article.

45. The improved device as recited in claim 43, wherein the electromagnetic radiation emitter is optically connected to a laser by way of an optical fiber.

46. The improved device as recited in claim 43, further comprising a chromophore compounded with the polymeric article.

47. The improved device as recited in claim 46, wherein the chromophore is thermochromatic.

48. The improved device as recited in claim 43, further improved in comprising the polymeric article disposed on the article forming member and a sheath covering the article and

- 55 -

the forming member and being retractable to expose the polymeric article.

49. A device for implanting a formable polymeric article into a patient which comprises:

a) an elongated tubular shaft having a distal end, a proximal end and a lumen communicating with an article shaping element;

b) an article shaping element positioned near the distal end of the tubular shaft, the article shaping element constructed and arranged to carry the formable polymeric article;

c) at least one optical fiber having a distal end communicating with an optical emitter, the emitter positioned in the proximity of the article shaping element and having a light-scattering characteristic.

50. The device of claim 49 wherein the article shaping element is radially expandable.

51. The device of claim 50 wherein the article shaping element comprises a radially expandable balloon.

52. The device of claim 49 which further includes at least one radiopaque marker.

53. The device of claim 49 wherein the shaping element further includes a low surface energy outer surface.

54. The device of claim 49 which further includes an elongated, retractable sheath operatively coupled to the proximal end of the elongated tubular shaft and extending to the distal end of the elongated tubular shaft, the sheath being retractable to expose at least a portion of the shaping element.

- 56 -

55. The device of claim 54 wherein the sheath includes a tapered, radially expandable tip element.

56. The device of claim 55 wherein the element includes at least one slit.

57. The device of claim 49 which further includes, positioned in the proximity of the shaping element, a polymeric article comprised of a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape.

58. The device of claim 57 which further includes at least one retaining sleeve positioned to maintain the position of the polymeric article in the proximity of the shaping element.

59. A device for implanting a formable polymeric article into a patient which comprises:

a) a first elongated tubular shaft having a proximal end, a distal end, and a lumen;

b) a second elongated tubular shaft having a proximal end, a distal end, and a lumen, the second shaft being positioned within the lumen of the first shaft and the distal end of the second shaft extending beyond the distal end of the first shaft;

c) a radially expandable balloon having a proximal end and a distal end, the distal end of the balloon being secured near the distal end of the second shaft and the proximal end of the balloon being secured near the distal end of the first shaft; and

d) at least one optical fiber having a distal end communicating with an optical emitter, the emitter positioned

- 57 -

in the proximity of the balloon and having a light-scattering characteristic.

60. The device of claim 59 which further includes at least one radiopaque marker.

61. The device of claim 59 wherein the balloon further includes a low surface energy outer surface.

62. The device of claim 59 which further includes an elongated, retractable sheath extending from the proximal end of the first shaft to the distal end of the second shaft, the sheath being retractable to expose at least the balloon.

63. The device of claim 60 wherein the sheath includes a tapered, radially expandable tip element.

64. The device of claim 63 wherein the tip element includes at least one longitudinal slit.

65. The device of claim 59 which further includes, positioned on the balloon, a polymeric article comprised of a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape.

66. The device of claim 65 which further includes at least one retaining sleeve positioned at least proximally to the polymeric article to maintain the position of the article in the proximity of the shaping element.

67. A device for implanting a formable polymeric article in a coronary artery which comprises:

- 58 -

a) an elongated tubular shaft having a distal end, a proximal end, an inflation lumen, and a lumen suitable for containing a guidewire;

b) an inflatable balloon in fluid communication with the inflation lumen mounted near the distal end of the tubular shaft;

c) at least one optical fiber having a distal end communicating with an optical emitter, the emitter positioned in the proximity of the balloon and having a light-scattering characteristic;

d) a polymeric article positioned in the proximity of the balloon, the article comprising a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape; and,

e) an elongated retractable sheath extending from the proximal end to the distal end of the elongated tubular shaft and having a radially expandable tip, the sheath being retractable to expose the polymeric article.

68. The device of claim 67 which further includes at least one radiopaque marker.

69. The device of claim 67 which further includes at least one retaining sleeve positioned at least proximally to the polymeric article to maintain the position of the article in the proximity of the balloon.

70. In a polymeric article for placement in a body cavity or lumen, the improvement comprising:

the polymeric article constructed and arranged to absorb a wavelength range of visible or near-visible light produced by a light source such that, upon absorbing light produced by

- 59 -

the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape.

71. The improved polymeric article as recited in claim 70, wherein the article is further characterized in that its ability to absorb light in the wavelength range decreases when the article reaches a predetermined temperature.

72. The improved polymeric article as recited in claim 71, wherein the article includes a thermochromatic chromophore compounded therein.

73. A polymeric article comprised of a material that absorbs a wavelength range of visible or near-visible light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape.

74. An article as in claim 73 wherein the polymeric material is selected from the group consisting of polymers of caprolactones, anhydrides, lactides, glycolides, oxyalkylenes, and combinations thereof.

75. An article as in claim 74 wherein the polymeric material comprises a copolymer of at least two entities selected from the group consisting of caprolactones, anhydrides, lactides, oxyalkylenes, and glycolides.

76. An article as in claim 73 wherein the polymeric material further contains a chromophore.

77. An article as in claim 76 wherein the chromophore comprises a dye or pigment.

- 60 -

78. An article as in claim 77 wherein the dye or pigment is selected from the group consisting of indocyanine, eosin, copper phthalocyanine, and combinations thereof.

79. An article as in claim 73 wherein the polymer is biodegradable.

80. An article as in claim 73 wherein the article is constructed and arranged to be implanted into a patient.

81. An article as in claim 73 wherein the article is constructed and arranged to be implanted into a body tissue having a lumen, the lumen defining an interior diameter.

82. An article as in claim 81 wherein the first shape has an outer diameter that is smaller than the interior diameter defined by the lumen.

83. An article as in claim 81 wherein the second shape has an outer surface conforming to the lumen.

84. An article as in claim 80 wherein the article is constructed and arranged to be implanted into a hollow organ having an interior surface defining a cavity.

85. An article as in claim 84 wherein the first shape is small enough to be inserted into the cavity.

86. An article as in claim 84 wherein the second shape has an outer surface conforming to the interior surface of the hollow organ.

87. An article as in claim 80 wherein the article is constructed and arranged to be deposited onto a tissue surface.

- 61 -

88. An article as in claim 87 wherein the second shape has a surface conforming to the tissue surface.

89. An article as in claim 73 wherein the article contains a therapeutic agent.

90. An article as in claim 73 wherein at least the second shape includes at least one aperture.

91. An article as in claim 73 wherein the second shape comprises a plurality of discontinuous domains.

92. An article as in claim 87, further characterized in being a polymeric film suitable for coating a tissue surface

93. An article as in claim 92, wherein said polymeric film has at least one biocompatible surface.

94. A polymeric article comprising a polymeric material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape, the article further characterized in that its ability to absorb light in the wavelength range decreases when the article reaches a predetermined temperature.

95. The article of claim 94 wherein the polymeric material comprises a polymer or copolymer of materials selected from the group consisting of caprolactones, anhydrides, lactides, glycolides, and combinations thereof.

96. The article of claim 94 wherein the polymeric material contains a thermochromic dye having a lower critical temperature and an upper critical temperature.

- 62 -

97. The article of claim 94 wherein the polymeric material further contains a non-thermochromic chromophore.

98. The article of claim 96 wherein the polymeric material has a melting temperature between the lower critical temperature and the upper critical temperature.

99. A method for implanting a moldable polymeric article in a coronary artery which comprises the steps of:

a) providing a device which comprises:

i) an elongated tubular shaft having a distal end, a proximal end, an inflation lumen, and a lumen suitable for containing a guidewire;

ii) an inflatable balloon in fluid communication with the inflation lumen mounted near the distal end of the tubular shaft;

iii) at least one optical fiber having a distal end communicating with an optical emitter, the emitter positioned in the proximity of the balloon and having a light-scattering characteristic;

iv) a polymeric article positioned in the proximity of the balloon, the article comprising a material that absorbs a wavelength range of light produced by a light source, the article constructed and arranged such that, upon absorbing light produced by the source, the article becomes sufficiently fluent to allow it to be molded from a first shape to a second shape; and,

v) an elongated retractable sheath extending from the proximal end to the distal end of the elongated tubular shaft and having a radially expandable tip, the sheath being retractable to expose the polymeric article;

b) guiding the distal end of the device to position the polymeric article at a desired location in the artery;

c) retracting the sheath to expose the polymeric article;

- 63 -

d) directing light through said at least one optical fiber to the polymeric article at least until the polymeric article becomes heated to a temperature at which it becomes moldable;

e) inflating the balloon to mold the polymeric article into contact with the artery;

f) allowing the polymeric article to cool;

g) deflating the balloon; and,

h) withdrawing the elongated tubular shaft from the patient, thereby leaving the polymeric article in position at the treatment location.

100. A method for molding a polymeric article which comprises the steps of:

a) providing a polymeric material that absorbs light in a wavelength range of light produced by a light source;

b) illuminating the polymeric material with sufficient light from the source to heat the material to at least the temperature at which the material becomes fluent;

c) molding the fluent material into a desired shape; and

d) allowing the material to cool and become non-fluent.

101. A method as in claim 100 wherein the light is of a wavelength range that is not readily absorbed by human tissue.

102. A method as in claim 101 wherein the wavelength range of the light is in a spectrum of between about 500 and 850 nm.

103. A method as in claim 100 wherein the light source comprises a laser.

104. A method as in claim 100 wherein the polymeric material is selected from the group consisting of polymers of caprolactones, anhydrides, lactides, glycolides, lower alkylene oxides, and combinations thereof.

- 64 -

105. A method as in claim 104 wherein the polymeric material comprises a copolymer of at least two moieties selected from the group consisting of caprolactones, anhydrides, lactides, and glycolides.

106. A method as in claim 100 wherein the polymeric material further contains a chromophore.

107. A method as in claim 106 wherein the chromophore comprises a dye or pigment.

108. A method as in claim 107 wherein the dye or pigment is selected from the group consisting of indocyanine, eosin, copper phthalocyanine, and combinations thereof.

109. A method as in claim 100 wherein the polymer is biodegradable.

110. A method as in claim 100 wherein the fluent polymer is molded using a catheter having a radially expandable portion.

111. A method as in claim 110 wherein the radially expandable portion of the catheter comprises a dilatation balloon.

112. A method as in claim 100 which further includes the step of determining when the polymeric material becomes fluent.

113. A method as in claim 112 wherein the determining step includes monitoring the pressure or volume of an expandable portion of a catheter.

INTERNATIONAL SEARCH REPORT

In tional Application No
PCT/US 94/04824

A. CLASSIFICATION OF SUBJECT MATTER
IPC 5 A61F2/06 A61B17/22

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 5 A61F A61B B29C

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US,A,5 100 429 (SINOFSKY ET AL.) 31 March 1992 see the whole document	43-70, 73-75, 79-88, 90-95, 100-105, 109-111

* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
- "&" document member of the same patent family
